Directive System for Maps' Guided System Based on API

Criterion E-Evaluation

[Refer to **Appendix II & III – Client Feedback & Final Interview**]

Success Criteria	Status
Have the ability to login, preserve and protect the data.	Achieved: The type-in password will be hidden. If the login account and password mismatch with the either account and password in the database will alert the user and avoid unauthorized access into the system. For registration, if the users input account match with the current account registered, the system will alert the users, to avoid problem of different same account. The login and register buttons successfully cross-check within the data inside MYSQL database.
Construct a user-friendly GUI	Achieved: The GUI is clean and directive, each text-field well remind users what should be type into the box and different usage of the button.
With a necessary text-field to enter searching information.	Achieved: text-field automatically display destination based on key-words type-in by users
The users can clearly check their research and travelling history, and edit.	Achieved: In the html form, the table well-perform the sequence number, searched destination and time of the research history. As well as the related travelling latitude and longitude. The data store in MYSQL database clearly present in a form of table. All the data presented can be edited by users and simultaneously auto-refreshing the page for users. Editing buttons are well-functioned and all changes are relatively connected to database.
Able to present different types of travelling (bus, car).	Achieved: Three ways of travelling bus, car and on feet are presented to users. Except for walking, both bus and car travelling enable users to choose their travelling mode, such as fastest or cheapest.
Enable users to check their own point of interest (POI).	Achieved: The relative position can be found by entering POI.
Able to check the surroundings of destination and starting point.	Achieved: Users are able to research the surrounding of destination and starting point by entering the keyword of two different modes (Study and Causal), offer users different using experiences. Additionally, the bus stops nearby users' current position will also be marked and displayed on the map. Through navigation system, users can find the bus stops.

System is able to locate users' current position.	Achieved: Through the types of web-browsers, website is able to locate the current position of users, and demonstrate the related real-time weather.
Users are able to choose different modes.	Achieved: Users will have different experience based on the mode they choose.
Accept multiple-users' access.	Achieved: Users can get access to the website through the specific ports, and ports allow multiple users who can use the website function.

Possible future improvement:

1. **Device Variability**: To allow smartphones or IPAD users to get access to the system, optimized the websites to fit in different types and size of hardware. As mentioned in Appendix I, the website will be used daily, so the navigation services should function correctly on different devices models.
2. **Enhance quality of using API**:
   a) By using the cache memory inside the client's webpage, to buffer the retrieved data, so avoid the repetitive request for same data. Server buffer memory can also be used in the same way.
   b) Implementation of HTTP/2 protocol, which to reduce the network latency and increase the speed of page loading of clients by compressing the data header field of the HTTP header field.
3. **Hazards reminder and routine recommendation**: Due to the complexity and variability of weather, natural disaster in some area may happened. The system should summarize the local weather and alert a piece of short information to recommend users whether the weather is fit to go out.
